(57) **ABSTRACT**

A device for creating turbulent flow in a fluid including a tank having an inlet, an outlet, and an interior; at least one jet in an inflow assembly in the interior of the tank, the jet being in fluid communication with the inlet, the jet circulating fluid in the tank; a plurality of holes in an outflow assembly in the interior of the tank, the plurality of holes being in fluid communication with the outlet; and a deflector positioned to circulate the bulk of the fluid away from the plurality of holes. Methods of using the device are also provided.

TURBULENT FLOW DEVICES AND METHODS OF USE

This application claims priority of U.S. Provisional Application No. 61/775,889, filed Mar. 11, 2013, entitled “Turbulent Flow Devices and Methods of Use”, the contents of which are hereby incorporated by reference.

FIELD OF THE INVENTION

This invention relates to devices for increasing turbulent flow in a fluid and methods of using such devices. In particular, the invention relates to increasing turbulent flow in a fluid to maximize contact between material such as Sphagnum moss leaves contained in a mesh bag and preventing the bag from occluding outflow from the device.

BACKGROUND OF THE INVENTION

There have been earlier devices used to treat water that involved increasing the contact between the water treatment substances and the water. See, for example, U.S. Pat. No. 6,080,304, which describes a clarifying device for use in an aquarium.

Sphagnum moss has been used to treat water. Previous studies have demonstrated that Sphagnum moss significantly inhibits the growth of free-floating (planktonic) bacteria. See U.S. Pat. No. 7,497,947 B2 and U.S. Patent Application Publication No. 2006/0032124 A1, both of which are incorporated by reference herein. Other studies have demonstrated that Sphagnum moss inhibits and removes biofilm (U.S. Patent Application Publication No. 2012/0152828 A1) and that moss can be used to reduce disinfection by-products in water treated with disinfectants (U.S. Patent Application Publication No. 2013/0140239 A1). “Sphagnum moss” is a generic expression that designates a range of botanical species that co-exist in a sphagnum bog. It should be noted that “peat moss” refers generally to a decomposed or composted Sphagnum moss such as that found in a bog containing Sphagnum moss. Sphagnum moss is commonly harvested for use in various products. The petals, and not the stems, of the moss preferably may be harvested. Typically large pieces of plant material (roots, twigs, etc.) are removed. Excess water is removed and the moss is air dried. The moss may be compressed prior to packaging or shipment. The dried and compressed Sphagnum moss petals preferably are contained in a fine mesh bag that allows flow of water in and out of the bag but contains the petals within the bag. Various additives may be used to alter the absorption characteristics or mechanical properties of the moss. Because Sphagnum moss is readily available and relatively inexpensive, it has been used in a variety of products, primarily for the absorption of fluids.

There is need in the art for devices and methods of increasing turbulent flow in a fluid, particularly for contacting water treatment substances with water to improve the efficiency of the water treatment substances such as water.

SUMMARY OF THE INVENTION

The invention provides a device for creating turbulent flow in a fluid comprising: a tank having an inlet, an outlet, and an interior; at least one jet in an inflow assembly in the interior of the tank, the jet being in fluid communication with the inlet, the jet circulating fluid in the tank; a plurality of holes in an outflow assembly in the interior of the tank, the plurality of holes being in fluid communication with the

2

outlet; and a deflector positioned to circulate the bulk of the fluid away from the plurality of holes.

The invention provides a method of producing turbulence in a fluid comprising: providing the device of the preceding paragraph, pumping fluid into the inlet, and allowing fluid to flow out the outlet.

The invention provides a method of contacting moss with water comprising: providing the device described two paragraphs above, placing moss in the interior of the tank, pumping water into the inlet, and allowing water to flow out the outlet.

The invention provides a method of contacting a solid material with a fluid comprising: providing the device described three paragraphs above, placing the solid material in the interior of the tank, introducing the fluid into the inlet, and allowing the fluid to flow out the outlet.

It is to be understood that both the foregoing general description and the following detailed description are exemplary and explanatory and are intended to provide further explanation of the invention as claimed.

BRIEF DESCRIPTION OF THE DRAWINGS

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

The invention provides a device for creating turbulent flow in a fluid comprising: a tank having an inlet, an outlet, and an interior; at least one jet in an inflow assembly in the interior of the tank, the jet being in fluid communication with the inlet, the jet circulating fluid in the tank; a plurality of holes in an outflow assembly in the interior of the tank, the plurality of holes being in fluid communication with the outlet; and a deflector positioned to circulate the bulk of the fluid away from the plurality of holes. Throughout this application, including the claims, a “jet” is any structure from which fluid flows out at a rapid speed. Throughout this application, including the claims, “turbulent flow” merely means agitated water and not the more technical definition from fluid dynamics.

In one embodiment, the inflow assembly comprises a first jet and a second jet. In an embodiment, the first and second jets are oriented at a right angle to each other. In an embodiment, the tank has a top portion and a side portion and the first jet is pointed at the top portion and the second jet is pointed at the side portion. In an embodiment, the inlet is positioned above the outlet. In one embodiment, the deflector is attached to the outflow assembly. In an embodiment, the deflector is a curved rectangular sheet. In one embodiment, the deflector has dimensions of from 8 to 16 inches (20 to 41 cm) by 8 to 16 inches (20 to 41 cm) by 1/8 to 1/2 inch (0.32 to 1.3 cm). In an embodiment, the deflector is a rectangular sheet. In one embodiment, the interior of the tank has a vertical height and wherein the plurality of holes are located near the midpoint of the vertical height of the interior of the tank. In an embodiment, the deflector is near and in front of the plurality of holes. In an embodiment, the inflow assembly comprises exactly two jets. In one embodiment, the inflow assembly comprises exactly three jets. In an embodiment, the device is configured to direct the fluid in a generally clockwise or counter-clockwise direction.

The invention provides a method of producing turbulence in a fluid comprising: providing a device for creating turbulent flow in a fluid, pumping a fluid into the inlet, and allowing fluid to flow out the outlet, the device comprising a tank having an inlet, an outlet, and an interior; at least one jet in an inflow assembly in the interior of the tank, the jet being in fluid communication with the inlet, the jet circulating fluid in the tank; a plurality of holes in an outflow assembly in the interior of the tank, the plurality of holes being in fluid communication with the outlet; and a deflector positioned to circulate the bulk of the fluid away from the plurality of holes. In an embodiment, the fluid is water.

The invention provides a method of contacting moss with water comprising: providing a device for creating turbulent flow in a fluid, placing moss in the interior of the tank, pumping water into the inlet, and allowing water to flow out the outlet, the device comprising a tank having an inlet, an outlet, and an interior; at least one jet in an inflow assembly in the interior of the tank, the jet being in fluid communication with the inlet, the jet circulating fluid in the tank; a plurality of holes in an outflow assembly in the interior of the tank, the plurality of holes being in fluid communication with the outlet; and a deflector positioned to circulate the bulk of the fluid away from the plurality of holes. In one embodiment, water is pumped into the inlet at a rate of 15 to 35 gallons (57 to 132 liters) per minute. In an embodi-

4

ment, the tank has a volume of 50 to 100 gallons (190 to 380 liters). The tank could have any volume large enough to allow flow of fluid from one pint to hundreds or thousands of gallons.

In one embodiment, the moss is in one or more mesh bags. The mesh bags need to have spaces in the mesh small enough to contain particles of moss and large enough to allow free passage of water within the bag. In an embodiment, the inlet assembly comprises a first jet and a second jet. In an embodiment, the first and second jets are oriented at a right angle to each other. In an embodiment, the tank has a top portion and a side portion and the first jet is pointed at the top portion and the second jet is pointed at the side portion. In an embodiment, the inlet is positioned above the outlet. In one embodiment, the deflector is attached to the outlet assembly. In an embodiment, the deflector is near and in front of the plurality of holes. In one embodiment, the moss is regenerated by flowing an acidic or salt solution through the device. In an embodiment, the inflow assembly comprises exactly two jets. In one embodiment, the inflow assembly comprises exactly three jets. In an embodiment, the device is configured to direct the fluid in a generally clockwise or counter-clockwise direction.

The invention provides a method of contacting a solid material with a fluid comprising: providing a device for creating turbulent flow, placing the solid material in the interior of the tank, introducing the fluid into the inlet, and allowing the fluid to flow out the outlet, the device comprising a tank having an inlet, an outlet, and an interior; at least one jet in an inflow assembly in the interior of the tank, the jet being in fluid communication with the inlet, the jet circulating fluid in the tank; a plurality of holes in an outflow assembly in the interior of the tank, the plurality of holes being in fluid communication with the outlet; and a deflector positioned to circulate the bulk of the fluid away from the plurality of holes. In an embodiment, the inlet assembly comprises a first jet and a second jet. In one embodiment, the first and second jets are oriented at a right angle to each other. In an embodiment, the tank has a top portion and a side portion and the first jet is pointed at the top portion and the second jet is pointed at the side portion. In an embodiment, the inlet is positioned above the outlet. In an embodiment, the deflector is attached to the outlet assembly. In an embodiment, the deflector is near and in front of the plurality of holes.

The devices of the invention can be used to contact any fluid with any material, for example particles, spheres, leaves, petals, etc. The device maximizes the exposure of the fluid to the material to facilitate interaction of the fluid and the material and diffusion of substances out of the material into the fluid or out of the fluid into the material.

The devices of the invention can be used to expose particles, leaves, petals, etc. in one or more mesh bags to turbulent flow of a fluid in a continuous flow situation while not allowing the bags to obstruct the outflow of the device. The deflector directs the fluid flow away from the outflow holes and thereby prevents the bags and the contents of the bags from obstructing the outflow holes. In an embodiment, the jets are positioned to provide directed flow around the horizontal and vertical circumference of the vessel, across the deflector plate, and out the outlet without allowing the bags to be sucked into the outflow and thus obstructing flow.

Preferred embodiments of the invention are described with reference to the accompanying drawings.

FIG. 1 shows a turbulent flow device 100 of the invention. The device includes a tank 110, tank inlet 120, tank outlet 130, and tank cover 140. Tank 110 has a top portion 112 and

5

a side portion **114**. The tank **110** is a commercially available tank that is intended to be filled with sand and used to filter water. Suitable tanks are available from Waterco, Augusta, Ga., USA. The tank can be any size, but preferably has an interior diameter of approximately 40 inches (100 cm), 36 inches (91 cm), 30 inches (76 cm), 28 inches (71 cm), 24 inches (61 cm), or 19 inches (48 cm), and a height of approximately 30 inches (76 cm). The tank can have any volume, but preferably has a volume from 50 to 100 gallons (190 to 380 liters). The tank can be made of metal or fiberglass. The tank cover **140** includes a bleed assembly **142** that is included when the tank is purchased from Waterco. The bleed assembly **142** is used to bleed air from the tank.

As shown in FIGS. 2 and 3, which are cut-away views of the turbulent flow device **100** of FIG. 1, inflow assembly **200** is connected to tank inlet **120** and outflow assembly **300** is attached to tank outlet **130**. Deflector **400** is attached to the outflow assembly **300** by deflector connection **410**. FIG. 4 is a cross-sectional view from line 4-4 of FIG. 1 and FIG. 5 is a cross-sectional view from line 5-5 of FIG. 1. The deflector **400** preferably has dimensions of from 8 to 16 inches (20 to 41 cm) by 8 to 16 inches (20 to 41 cm) by $\frac{1}{8}$ to $\frac{1}{2}$ inch (0.32 to 1.3 cm), and more preferably has dimensions of 12 inches by 12 inches by $\frac{1}{8}$ inch (30 cm×30 cm×0.32 cm). As shown in the figures, deflector **400** is a rectangular sheet that has been curved to direct fluid past the outflow assembly **300**. The deflector **400** is preferably made of a flexible plastic and the inlet and outflow assemblies are preferably made of plastic such as polyvinylchloride (PVC). The deflector **400** could have rounded edges and corners.

The inflow assembly **200** includes a forward jet **210** and a side jet **220**. The side jet **220** directs the incoming fluid in a counter-clockwise direction as viewed from the top of the tank **110** shown in FIG. 2. The forward jet **210** increases the turbulence of the fluid in the tank. The inflow assembly **200** is shown in detail in FIG. 6. The inflow assembly **200** is mounted to the tank **110** with the aid of the inlet bulkhead **230**. The inflow assembly **200** can be connected to the tank **110** by adhesive or other methods. The fluid enters the inlet assembly **200** through a pipe **240** having an inside diameter of approximately 2 inches (5 cm), the inside diameter is reduced to approximately 1 inch (2.5 cm) at pipe **250**, and the fluid then flows out of forward jet outlet **212** and side jet outlet **222**.

The outflow assembly **300**, without the deflector **400** attached, is shown in FIGS. 7 and 8. The outflow assembly **300** is mounted to the tank **110** with the aid of the outlet bulkhead **330**. The outflow assembly **300** can be connected to the tank **110** by adhesive or other methods. Fluid flows into the outlet assembly through holes **360** on pipe **350**. Fluid also flows into the outlet assembly through hole **380** on cap **370**. After fluid enters holes **360** and **380**, the fluid flows through pipe **350** and out tank outlet **130**. Pipe **350** has an inside diameter of approximately 2 inches (5 cm).

The deflector **400** (not shown in FIG. 7) is attached to the outflow assembly by the deflector connection **410**. As shown in FIG. 7, the deflector connection has two parts, one above the inlet holes **360** and one below the inlet holes **360**. The deflector can be connected to the deflector connection by bolts, rivets, adhesives, or other methods.

In use, a fluid such as water is introduced into the tank **110** through the tank inlet **120**. If the fluid is water, water preferably is introduced at a rate of 15 to 35 (57 to 132 liters) gallons per minute, more preferably at about 15 gallons (57 liters) per minute. The speed of flow out of the forward jet

6

outlet **212** and side jet outlet **222** preferably ranges from 2.5 ft/sec to 6 ft/sec (0.76 m/sec to 1.8 m/sec) at 10 to 20 gallons (38 to 76 liters) per minute.

The fluid enters the inlet assembly **200** through a pipe **240** having an inside diameter of approximately 2 inches, the inside diameter is reduced to approximately 1 inch (2.5 cm) at pipe **250**, and the fluid then flows out of forward jet outlet **212** and side jet outlet **222**. The side jet **220** directs the incoming fluid in a counter-clockwise direction as viewed from the top of the tank **110** shown in FIG. 2. The forward jet **210** increases the turbulence of the fluid in the tank.

The fluid exits through the outflow assembly **300**. Fluid flows into the outlet assembly through holes **360** and **380**. After fluid enters holes **360** and **380**, the fluid flows through pipe **350** and out tank outlet **130**. Deflector **400** prevents material that may be in the fluid from clogging the holes **360** and **380** by deflecting the circulating fluid from the holes **360** and **380**.

FIG. 9 shows another embodiment of a turbulent flow device **1100** of the invention. The device includes a tank **1110**, tank inlet **1120**, tank outlet **1130**, and tank cover **1140**. The tank cover **1140** includes a bleed assembly **1142**. The bleed assembly **1142** is used to bleed air from the tank.

As shown in FIGS. 10 and 11, which are cut-away views of the turbulent flow device **1100** of FIG. 9, inflow assembly **1200** is connected to tank inlet **1120** and outflow assembly **1300** is attached to tank outlet **1130**. Deflector **1400** is attached to the outflow assembly **1300** by deflector connection **1410**. FIG. 12 is a cross-sectional view from line 12-12 of FIG. 9 and FIG. 13 is a cross-sectional view from line 13-13 of FIG. 9. As shown in the figures, deflector **1400** is a rectangular sheet that directs fluid past the outflow assembly **1300**. The deflector **1400** is preferably made of plastic and the inlet and outflow assemblies are preferably made of plastic such as polyvinylchloride (PVC). The deflector **1400** could have rounded edges and corners.

The inflow assembly **1200** includes a jet **1210** and a jet **1220**. The jet **1220** directs the incoming fluid in a clockwise direction as viewed from the top of the tank **1110** shown in FIG. 10. The jet **1210** increases the turbulence of the fluid in the tank. The inflow assembly **1200** is mounted to the tank **1110**. The inflow assembly **1200** can be connected to the tank **1110** by adhesive or other methods. The fluid enters the inlet assembly **1200** through a pipe having an inside diameter of approximately 2 inches (5 cm), and the fluid flows out of jet outlet **1212** and jet outlet **1222**.

The outflow assembly **1300** can be connected to the tank **1110** by adhesive or other methods. Fluid flows into the outlet assembly through holes **1360** on pipe **1350**. Fluid also flows into the outlet assembly through hole **1380** on cap **1370** (not shown, similar to FIG. 8). After fluid enters holes **1360** and **1380**, the fluid flows through pipe **1350** and out tank outlet **1130**. Pipe **1350** has an inside diameter of approximately 2 inches (5 cm).

The deflector **1400** is attached to the outflow assembly by the deflector connection **1410**. The deflector can be connected to the deflector connection by bolts, rivets, adhesives, or other methods.

FIG. 14 shows another embodiment of a turbulent flow device **2100** of the invention. The device includes a tank **2110**, tank inlet **2120**, tank outlet **2130**, and tank cover **2140**. The tank cover **2140** includes a bleed assembly **2142**. The bleed assembly **2142** is used to bleed air from the tank.

As shown in FIGS. 15 and 16, which are cut-away views of the turbulent flow device **2100** of FIG. 14, inflow assembly **2200** is connected to tank inlet **2120** and outflow assembly **2300** is attached to tank outlet **2130**. Deflector

2400 is attached to the outflow assembly **2300** by deflector connection **2410**. FIG. 17 is a cross-sectional view from line 17-17 of FIG. 14 and FIG. 18 is a cross-sectional view from line 18-18 of FIG. 14. As shown in the figures, deflector **2400** is a rectangular sheet that directs fluid past the outflow assembly **2300**. The deflector **2400** is preferably made of plastic and the inlet and outflow assemblies are preferably made of plastic such as polyvinylchloride (PVC). The deflector **2400** could have rounded edges and corners.

The inflow assembly **2200** includes a jet **2210** and a jet **2220**. The jet **2220** directs the incoming fluid in a clockwise direction as viewed from the top of the tank **2110** shown in FIG. 15. The jet **2210** increases the turbulence of the fluid in the tank. The inflow assembly **2200** is mounted to the tank **2110**. The inflow assembly **2200** can be connected to the inlet assembly **2200** through a pipe having an inside diameter of approximately 2 inches (5 cm), and the fluid flows out of jet outlet **2212** and jet outlet **2222**.

The outflow assembly **2300** can be connected to the tank **2110** by adhesive or other methods. Fluid flows into the outlet assembly through holes **2360** on pipe **2350**. Fluid also flows into the outlet assembly through hole **2380** on cap **2370** (not shown, similar to FIG. 8). After fluid enters holes **2360** and **2380**, the fluid flows through pipe **2350** and out tank outlet **2130**. Pipe **2350** has an inside diameter of approximately 2 inches (5 cm).

The deflector **2400** is attached to the outflow assembly by the deflector connection **2410**. The deflector can be connected to the deflector connection by bolts, rivets, adhesives, or other methods.

FIG. 19 shows another embodiment of a turbulent flow device **3100** of the invention. The device includes a tank **3110**, tank inlet **3120**, tank outlet **3130**, and tank cover **3140**. The tank cover **3140** includes a bleed assembly **3142**. The bleed assembly **3142** is used to bleed air from the tank.

As shown in FIGS. 20 and 21, which are cut-away views of the turbulent flow device **3100** of FIG. 19, inflow assembly **3200** is connected to tank inlet **3120** and outflow assembly **3300** is attached to tank outlet **3130**. Deflector **3400** is attached to the outflow assembly **3300** by deflector connection **3410**. FIG. 22 is a cross-sectional view from line 22-22 of FIG. 19 and FIG. 23 is a cross-sectional view from line 23-23 of FIG. 19. As shown in the figures, deflector **3400** is a rectangular sheet that directs fluid past the outflow assembly **3300**. The deflector **3400** is preferably made of plastic and the inlet and outflow assemblies are preferably made of plastic such as polyvinylchloride (PVC). The deflector **3400** could have rounded edges and corners.

The inflow assembly **3200** includes a jet **3210**, a jet **3220**, and a jet **3205**. The jets **3220** and **3210** direct the incoming fluid in a clockwise direction as viewed from the top of the tank **3110** shown in FIG. 20. The jet **3205** increases the turbulence of the fluid in the tank. The inflow assembly **3200** is mounted to the tank **3110**. The inflow assembly **3200** can be connected to the tank **3110** by adhesive or other methods. The fluid enters the inlet assembly **3200** through a pipe having an inside diameter of approximately 2 inches (5 cm), and the fluid flows out of jet outlet **3212**, jet outlet **3222**, and jet outlet **3207**.

The outflow assembly **3300** can be connected to the tank **3110** by adhesive or other methods. Fluid flows into the outlet assembly through holes **3360** on pipe **3350**.

Fluid also flows into the outlet assembly through hole **3380** on cap **3370** (not shown, similar to FIG. 8). After fluid enters holes **3360** and **3380**, the fluid flows through pipe

3350 and out tank outlet **3130**. Pipe **3350** has an inside diameter of approximately 2 inches (5 cm).

The deflector **3400** is attached to the outflow assembly by the deflector connection **3410**. The deflector can be connected to the deflector connection by bolts, rivets, adhesives, or other methods.

In a preferred embodiment, the turbulent flow device **100** is used to increase the efficiency of contact between moss and water. The moss is contacted with the water for the purposes described above, especially in the background of the invention. If the turbulent flow device **100** is used to contact water in a home water system a single bag of moss can be used in the device. If the device **100** is used to contact water in a pool system, more bags can be used, for example 8 to 12 bags. Preferably, each bag of moss is made of nylon mesh and contains three 50 g bricks. The moss was obtained from Coastpak Holdings, Ltd., Hokitika, New Zealand.

Deflector **400** prevents the moss bags and any moss that may escape from the bags from clogging the holes **360** in the outflow assembly **300**. The moss is naturally buoyant so it tends to stay in suspension. The water circulation should be maintained at a high enough velocity for the bags to get by the suction of the outflow holes **360** and maintain circulation of the bags in the vessel. Turbulent flow devices **1100**, **2100**, and **3100** can be used in a similar manner to turbulent flow device **100**.

In an embodiment, the moss is non-decomposed moss and is selected from the group consisting of *Sphagnum papillosum*, *Sphagnum cristatum*, and mixtures thereof.

In preferred embodiments, the moss is enclosed or encapsulated in a mesh material that prevents the moss from disintegrating in an aqueous environment. Preferred mesh materials include those comprising polymers such as nylon or polypropylene, with mesh sizes ranging from about 0.1 to 1 mm. Polymers are generally preferred because they are inexpensive and may be resistant to degradation.

Suitable for use in this invention are *Sphagnum papillosum*, which can be harvested from bogs in northern Minnesota, U.S.A., and *Sphagnum cristatum*, which is commercially available as a compressed board from Coastpak Holdings, Ltd., Hokitika, New Zealand and from Super-Sphag Ltd, Totara Flat, New Zealand. These species of moss can be used by themselves or together in the devices and systems of this invention. Typically and preferably the moss is cleaned to remove small particles, such as dirt, and larger debris, such as roots and leaves. Commercially available moss may be fumigated before it is packaged by a manufacturer in order to destroy seeds.

In a preferred embodiment, the moss is cut by mechanical means into a desired size and shape. The moss preferably is then sterilized by autoclaving, exposure to ethylene oxide, or by other means known to one of skill in the art. Sterilization destroys living organisms in the moss and thus avoids any problems of undesirable or foreign bacteria being introduced into the environment where a device of this invention is used. The moss is then ready for use.

The moss can be compressed and can be in the form of strips or bricks. The moss can be sterilized by autoclaving, sterilized by chemical treatment, or sterilized by treatment with ethylene oxide. The moss can be washed with an acidic solution, especially a solution of acetic acid. The moss can be washed with an acidic solution and then washed with a salt solution.

The devices **100**, **1100**, **2100**, and **3100** can be used to contact any fluid with any material to add or remove substances from the fluid or from the material.

9

The above description and the drawing are provided for the purpose of describing embodiments of the invention and are not intended to limit the scope of the invention in any way. It will be apparent to those skilled in the art that various modifications and variations can be made without departing from the spirit or scope of the invention. Thus, it is intended that the present invention cover the modifications and variations of this invention provided they come within the scope of the appended claims and their equivalents.

What is claimed is:

1. A method of contacting moss with water and producing turbulent flow in the water comprising:

providing a device for creating turbulent flow in a fluid comprising: a tank having an inlet, an outlet, and an interior; at least one jet in an inflow assembly in the interior of the tank, the jet being in fluid communication with the inlet, the jet circulating fluid in the tank; a plurality of holes in an outflow assembly in the interior of the tank, the plurality of holes being in fluid communication with the outlet; and a deflector positioned to circulate a bulk of the fluid away from the plurality of holes, the inflow assembly comprising a first jet and a second jet, and the tank having a top portion and a side portion and the first jet being pointed at the top portion and the second jet being pointed at the side portion,

10

placing moss in the interior of the tank,
pumping water into the inlet at a rate sufficient to produce turbulent flow in the water in the interior of the tank,
and

allowing water to flow out the outlet.

2. The method of claim 1, wherein the deflector is a curved rectangular sheet with dimensions of from 8 to 16 inches by 8 to 16 inches by $\frac{1}{8}$ to $\frac{1}{2}$ inch.

3. The method of claim 1, wherein water is pumped into the inlet at a rate of 15 to 35 gallons per minute.

4. The method of claim 1, wherein the tank has a volume of 50 to 100 gallons.

5. The method of claim 1, wherein the moss is in one or more mesh bags.

6. The method of claim 1, wherein the first and second jets are oriented at a right angle to each other.

7. The method of claim 1, wherein the inlet is positioned above the outlet.

8. The method of claim 1, wherein the deflector is attached to the outlet assembly.

9. The method of claim 1, wherein the moss is regenerated by flowing an acidic or salt solution through the device.
